## $\begin{array}{c} {\bf MGMT~237E:}\\ {\bf Empirical~Methods~in~Finance} \end{array}$

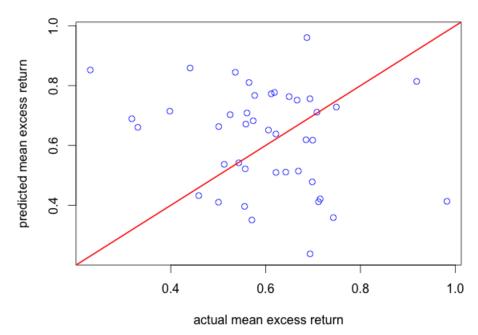

Homework 6

Yi-Chi Chan Zhaofang Shi Ahswin Kumar Ashok Kumar George Bonebright March 8, 2016 **1.a.** We can use time series regression on excess returns to test the Fama-French model on the industry portfolios. To do this, we will run a time series regression to estimate the values of  $\beta_i$ .

We use the formula:  $R^e_{it} = \alpha_i + \beta^m_i R^{e,m}_t + \beta^{smb}_i R^{smb}_t + \beta^{hml}_i R^{hml}_t + \epsilon_{it}$  as our regression model. There is no need to estimate risk prices because the factors are traded assests, therefore:  $\hat{\lambda} = (\lambda^m, \lambda^{smb}, \lambda^{hml})$  where  $\hat{\lambda}^j = \frac{1}{T} \sum_{t=1}^T \mathbf{R}^j_t for j = m, smb, hml$ . The coefficients  $(\beta^m_i, \beta^{smb}_i, \beta^{hml}_i)$  measure how the asset's return  $R^e_{it}$  covaries with the risk factors. The regression intercepts are the pricing errors and the should be zero under the null hypothesis.

We plot the predicted mean excess returns  $\hat{\beta}_i'\hat{\lambda}$  against the realized mean excess returns  $\bar{R}_{it}^e = \frac{1}{T} \sum_{t=1}^T R_{it}^e$ .

## FF Model on industry portfolios

**1.b.** Model testing  $H_0$ :pricing errors (alphas) are jointly zero.

We can test the model:  $E[R_{it}^e] = \beta_i' E[f_t]$  by running time series regressions:

We can test the model.  $E[R_{it}] = \beta_i E[f_t]$  by running time series regressions.  $R_{it}^e = \alpha_i + \beta_i' f_t = \epsilon_{it}, t = 1, ..., T$  with iid errors, homscedasticity, and independence of the factors, the test statistic for the pricing errors is given by:  $(T - K - N)/N[1 + \bar{f}'\hat{\Sigma}_f^{-1}\bar{f}^{-1}]\hat{\alpha}'\hat{\Sigma}_{\epsilon}^{-1}\hat{\alpha} \sim F_{N,T-N-K}$  where  $\hat{\Sigma}_{\epsilon}$  denotes the covariance matrix of  $\epsilon$ ,  $\hat{\Sigma}_f$  denotes the covariance matrix of the factors  $f_t$ ,  $\bar{f}$  is the average factor, and  $\hat{\alpha}$  are the OLS estimates of  $\alpha$ .

In this case, the F-statistic is 0.4184848 which is significant at the 99% confidence level for 43,626 degrees of freedom. We reject the null that the pricing errors are jointly zero.

**1.d.** The variation of industry portfolio returns are more dispersed than the variation in the 25 portfolios sorted by B/M ratios and size. It would be harder to explain the increased variance.
